

DOCKER AND CONTAINERS

Dr. Isaac Griffith Idaho State University

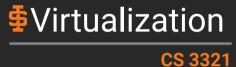

Outcomes

After today's lecture you will be able to:

- Docker
- Docker-Compose
- Basic idea of DockerHub

Advantages of Virtualization

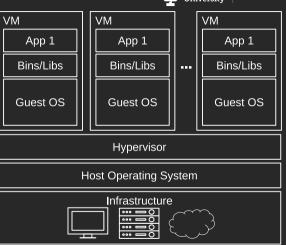

- Minimize hardware costs
 - Multiple virtual servers on one physical hardware
- Easily move VMs to other data centers
 - Provides disaster recovery. Hardware maintenance
 - Follow the sun (active users) or follow the moon (cheap power)
- Consolidate idle workloads. Usage is bursty and asynchronous
 - Increase device utilization
- Conserve power
 - Free up unused physical resources
- Easier automation
 - Simplified provisioning/administration of hardware and software
- Scalability and Flexibility: Multiple operating systems

Problems of Virtualization

Idaho State Computer Science

- Each VM requires an operating system (OS)
 - Each OS requires a license
 - Each OS has its own compute and storage overhead
 - Needs maintenance, updates

CS 3321

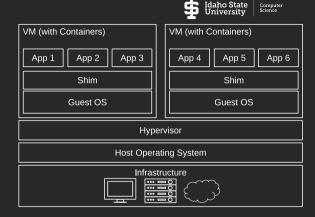

Solution: Containers

- Run many apps in the same virtual machine
 - These apps share the OS and its overhead
 - But these apps can't interfere with each another
 - · Can't access each other's resources without explicit permission
 - Like apartments in a complex

Containers

- Multiple containers run on one operating system on a virtual/physical machine
- All containers share the operating system
- Containers are isolated -> cannot interfere with each other
 - Own file system/data, own networking -> Portable

Containers

- Containers have all the good properties of VMs
 - Come complete with all files and data that you need to run
 - Multiple copies can be run on the same machine or different machine -> Scalable
 - Same image can run on a personal machine, in a data center or in a cloud
 - Operating system resources can be restricted or unrestricted as designed at container build time
 - Isolation: For example, "Show Process" (ps on Linux) command in a container will show only the processes in the container
 - Can be stopped. Saved and moved to another machine or for later run

VM vs. Containers

Impact on Legacy Application

High

Idaho State University

Criteria	VM	Containers
Image Size	3X	X
Boot Time	> 10s	~ 1s
Computer Overhead	> 10%	< 5%
Disk I/O Overhead	> 50%	Negligible
Isolation	Good	Fair
Security	Low-Medium	Medium-High
OS Flexibility	Excellent	Poor
Management	Excellent	Evolving

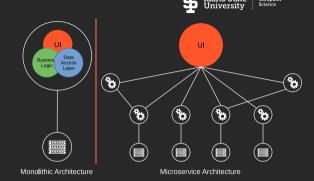

Low-Medium

CS 3321

Microservices

- Breaks large applications down into smaller executable components
- Easy to maintain and test
- Loosely coupled and can be deployed independently
- Can be combined with serverless architecture (i.e., AWS Lambda)

Why Use Docker

Idaho State Computer University

- Develop applications that work on any OS
- Easy to share applications among teams
- Easy to scale across multiple servers
- Large applications can be broken into multiple containers - one for each microservice

- Great solution for Cloud Computing
- Big community and library of Docker images

Serverless

Idaho State Com University

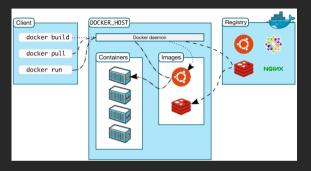

- Removes Dependency on infrastructure
- Allows developers to focus on application development
- Microservices can be decoupled with different cloud services
- Usually more cost effective

Docker

- Provides the isolation among containers
- Helps them share the OS
- Docker = Dock worker -> Manage containers
- Developed initially by Docker.com
- Downloadable for Linux, Windows, and Mac from docker.com
- Customizable with replacement modules from others

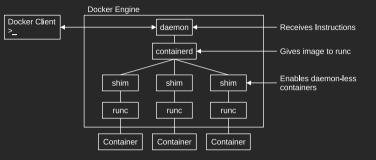

Docker

- Docker Engine: Runtime
- Two Editions:
 - Community Edition (CE): Free for experimentation
 - Enterprise Edition (EE): For deployment with paid support
- Written in the **Go** programming language from Google
- Download the community edition and explore

Docker Engine Components

- daemon: API and other features
- containerd: Execution logic.
 Responsible for container lifecycle.
 Start, stop, pause, unpause, delete containers
- runc: A lightweight runtime CLI

Image Registries

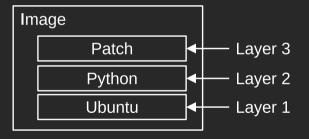

- Containers are built from images and can be saved as images
- Images are stored in registries
 - Local registry on the same host
 - Docker Hub Registry: Globally shared
 - Private registry on Docker.com
- Any component not found in the local registry is downloaded from specified location
- Official Docker Registry: Images vetted by Docker
- Unofficial Registry: Images not vetted (Use with care)
- Each image has several tags, e.g., v2, latest, ...
- Each image is identified by its 256-bit hash

Layers

- Each image has many layers
- Image is built layer by layer
- Layers in an image can be inspected by Docker commands
- Each layer has its own 256-bit hash
- For example:
 - Ubuntu OS is installed, then
 - Python package is installed, then
 - a security patch to Python is installed
- Layers can be shared among many containers

Building Container Images

Create a **Dockerfile** that describes the application, its dependencies and how to run it

```
FROM Alpine
LABEL maintainer="xx@gmail.com"
RUN apk add -update node;s -npm
COPY ./src
WORKDIR /src
RUN npm install
EXPOSE 8080
ENTRYPOINT ["node", "./app.js"]
```

Note: WORKDIR, EXPOSE, ENTRYPOINT result in tags. Others in Lavers

Docker commands

- docker run: Run the specified image
- docker start: start a stopped container
- docker stop: stop a container
- docker ps: shows the current process in a running container
- docker image 1s: list running containers
- docker rm: delete a container
- docker image rm: delete an image
- docker build: creates a new image from docker file

Open Container Initiative (OCI)

- A company called CoreOS defined alternative image format and container runtime API's
- Led to formation of OCI under Linux Foundation to govern container standards
 - OCI Image spec
 - OCI Runtime spec
- Everyone including Docker is now moving to or on OCI

Docker Compose

```
version: 3
services:
  sysad-mysql:
    image: mvsql:5.7
    environment.
      - "MYSQL_ROOT_PASSWORD=password"
    container_name: sysad-mysql
    restart: always
  sysad-apache2:
    image: sysad-crud
    ports:
    links:
      - "sysad-mysql"
    container_name: sysad-crud
    restart: always
    stdin_open: true
```

- Run multiple services in a single container
- Very useful for microservice applications
 - Service: Database
 - Service: Back-end server
 - Service: Front-end Web Client
- Specified as a docker-compose.yml file

Docker Swarm

- Orchestrates thousands of Containers
- \textcolor{Roarange}{\textbf{Swarm\textcolor{Roarange}}{\textbf{: a group of nodes collaborating over a network
- Two modes for Docker hosts:
 - Single Engine Mode: Not participating in a swarm
 - Swarm Mode: Participating in a Swarm
- A Service may run on a swarm
- Each swarm has a few managers that dispatch tasks to workers
 - Managers are also works (i.e., execute tasks)

Docker Swarm

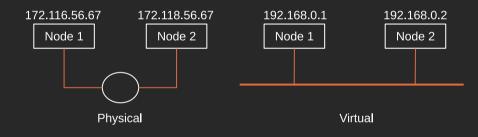

- The managers select a leader, who really keeps track of the swarm
- Assigns tasks, re-assigns failed worker's tasks, ...
- Other managers just monitor passively and re-elect a leader if the leader fails
- Services can be scaled up or down as needed
- Several Docker commands:
 - docker service: Manage services
 - docker swarm: Manage swarms
 - docker node: Manage nodes

Docker Overlay Networking

- Nodes in a swarm may not be in the same LAN
- VXLAN is used to provide virtual overlay networking

Docker Security

- All built-in security mechanisms in Linux are used and more
- Cryptographic node IDs
- Mutual Authentication
- Automatic Certificate Authority configuration
- Automatic Certificate Renewal on expiration
- **Encrypted Cluster Store**
- **Encrypted Network traffic**
- Signed images in Docker Content Trust (DCT)
- Docker Security Scanning detects vulnerabilities
- Docker secrets are stored in encrypted cluster store, encrypted transmission over network, and stored in in-memory file system when in use

Kubernetes

- Open Source Container Orchestration alternative
- Original source released by Google
- Cloud Native Computing Foundation (CNCF) project in Linux Foundation
- Pre-cursor to Swarms
- Facilities similar to Swarms
- A set of related containers is called a "Pod"
 - A Pod runs on a single host
- Swarm is called a "Cluster"
